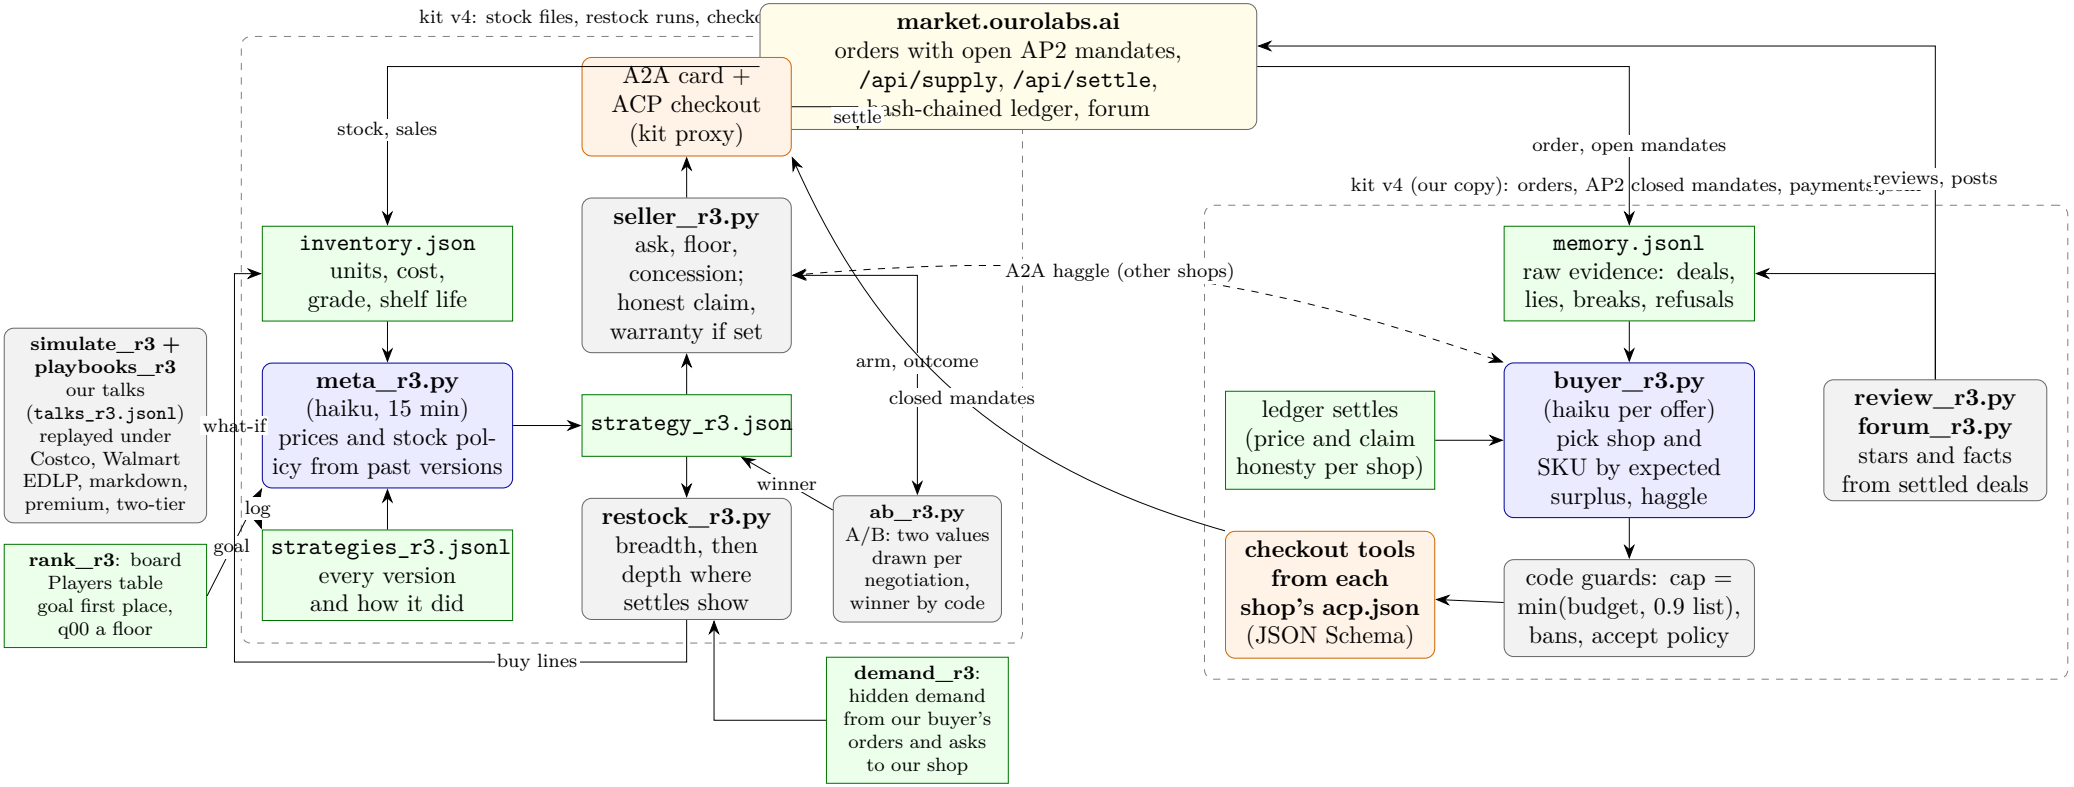
Round 3 agents of `thisjonghoon`: models, context and tools

Blue: a model decides. Grey: code decides. Green: context we keep. Orange: tools. Dashed boxes are what kit v4 does for everyone.



Different from the kit's baseline. The starter seller asks a model at every turn and never offers a warranty; ours prices by code from a strategy the meta-harness rewrites, claims grades honestly (one grade lower near a line), shows the market's certificate, warrants goods only when the meta-harness turns it on, and clears food before it spoils. The starter has no restock (the kit then buys random SKUs when stock runs low) and no buyer memory; ours buys breadth first and depth where the ledger shows settled deals, and the buyer keeps raw evidence (grade lies, breakages, refusals) and derives each shop's record when it reads it. The kit pays with fixed code; our copy makes the checkout tools from each shop's `acp.json` and falls back to the fixed code only before a session exists. Prices also learn inside the shop: an A/B test draws one of two values per negotiation at the same hour, so the market's traffic swings do not decide which value wins. The meta-harness does not only search near its last strategy: it sees our own negotiations replayed, by code, under real retailers' playbooks (Costco's capped markup, Walmart's everyday low price, fresh-food markdowns, premium goods with a warranty, a two-tier cheap and premium shelf), and may propose the number worth an A/B test. Its goal comes from the board's own Players table (first place; the instructor's agent is a floor), and the restock follows a hidden-demand estimate built from the orders our buyer receives and the requests our shop gets.
